## Introduction

- ▶ The Internet provides a *best-effort* service
  - ▶ Does not generally optimise for any particular user-centric metric
  - ▶ Measurement shows end-to-end paths generally suboptimal
- ▶ Overlay networks are widely deployed to improve Internet properties
  - ▶ Adding functionality, improving performance. . .
  - ▶ Feasible to deploy
- ▶ Detour routing is a generic form of overlay network
  - ▶ Redirecting arbitrary end-to-end traffic via tertiary nodes to change path properties
  - ▶ Challenge lies in discovering appropriate *detour* nodes

## Motivation

- ▶ Detour routing already shown to be effective for latency & availability
  - ▶ Easy and cheap metrics to measure
  - ▶ Good for real-time applications (VoIP, gaming ...)
  - ▶ Already used commercially (Akamai)
- ▶ Bandwidth is potentially much more useful metric to optimise
  - ▶ Can improve performance of any bulk-transfer application
  - ▶ File transfers, HD media streaming...
- ▶ However, bandwidth is both difficult and expensive to measure
  - ▶ Most work on bandwidth detouring either small-scale or analytical

## Overview

- ▶ Bandwidth as a metric
- ▶ Scope for detouring on the Internet today
- ▶ Exploiting detours

## Measuring Bandwidth

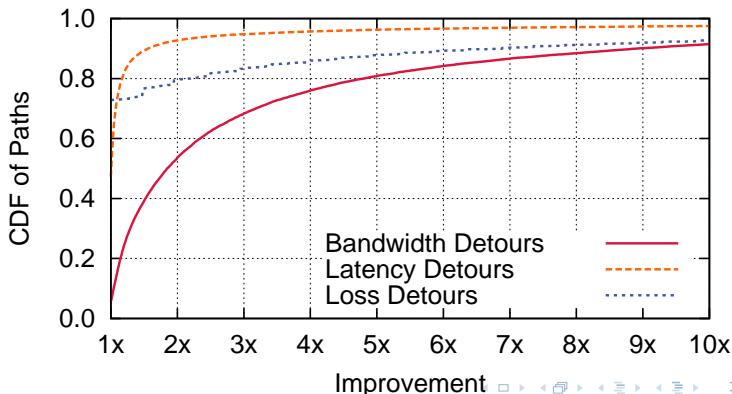

- ▶ Dataset: All-pairs Iperf bandwidth (BTC) measurements. 250 nodes, PlanetLab
- ▶ Iperf: Measures standard TCP connection
  - ▶ **Representative of application performance!**
  - ▶ Wastes a lot of bandwidth ( $\sim 10\text{MB}/\text{path}$ )
- ▶ Compared various “lightweight” analytical bandwidth estimation tools
  - ▶ Measuring via precisely timed packet bursts
  - ▶ Generally very slow. Give little insight into achievable throughput
- ▶ Developed our own estimation tool which wastes less bandwidth by detecting when TCP throughput has reached steady-state

## Bandwidth Observations

- ▶ Bandwidth is elastic
  - ▶ Introducing new traffic causes competing flows to back-off
  - ▶ Measurements extremely noisy
- ▶ Measurements consistent over moderate time intervals
  - ▶ Distribution of bandwidth variation in a 90 minute window is the same as over 30 seconds
  - ▶ Thus bandwidth detours can remain consistent over time
- ▶ **96.6% of paths can potentially benefit from bandwidth detouring!**
  - ▶ ie, for the vast majority of node-pairs, there exists another node to which they both have more bandwidth to than each other.

## Detouring for Bandwidth

- ▶ **Potential for improvement in bandwidth is much greater than for other metrics**
  - ▶ Little improvement available from multi-hop detours

## Exploiting Detours: IP Detouring

- ▶ Previous results based on analysis of measurements. We wish to evaluate real-world large-scale performance.
- ▶ Natural approach to building such a system would be to simply redirect IP packet flows via the detour node — **IP detouring**
  - ▶ Easily implemented with IP-in-IP tunneling and NAT.
  - ▶ Transparent to end nodes. Can be done anywhere en route.

## IP Detouring Performance

- ▶ End-to-end detour path properties composed from two constituent end-to-end IP paths.
  - ▶  $BW_{ABC} = \min(BW_{AB}, BW_{BC})$  ?
- ▶ IP detour path may have higher or lower latency than the existing “direct” path
  - ▶ Two complete end-to-end paths → more hops
  - ▶ Changes the loss characteristics, which **severely** affects TCP throughput.
- ▶ We have an equation which predicts the throughput of the IP detour path, defined terms of the throughputs and latencies of the constituent paths.

## TCP Detouring

- ▶ TCP throughput terrible on IP detour paths
- ▶ Sidestep by using a separate TCP connection over each of the constituent paths
  - ▶ Essentially split-TCP, except split outside rather than inside the network
- ▶ Implemented with customised SOCKS proxy and sockisfying library
  - ▶ Possible to do transparently in network, but complex
  - ▶ Still remains transparent to applications
- ▶ Would expect performance of detour paths to be roughly equivalent to the minimum of the two constituent paths. . .

## TCP Detouring Performance

- ▶ **Median BW: 12 → 21Mbps**
- ▶ Bottleneck at around 50Mbps (PlanetLab?)
- ▶ 36.7% of paths double in BW **and** improve by > 1Mbps

## Detour Discovery

- ▶ Detour routing relies upon discovering a good detour node for any given end-to-end path
  - ▶ Not scalable to have a complete picture of the network
- ▶ There are many effective proposals for discovering detours for latency
  - ▶ Previously we have proposed identifying detours for arbitrary paths using AS-path similarity-clustering based on existing known-good detourable paths.
  - ▶ This was effective and scalable for latency, but less so for bandwidth.
- ▶ **Using latency detours to identify bandwidth detours is no better than random selection.**
  - ▶ Need bandwidth specific approaches

## Ukairo: Generic Detour Routing Service

- ▶ Currently deploying large-scale dynamic platform on PlanetLab.
  - ▶ Measuring performance improvement for both intra-overlay applications (eg BT) and the public Internet (eg improving performance to third-party websites)
- ▶ Quantifying the extent to which Split-TCP improves paths, as compared to traversing alternative routes.
- ▶ Evaluating new detour discovery approaches
  - ▶ Latency-detouring has focused on the structural inefficiencies inherent in Internet routing. Approaches have been based on finding and exploiting “better” alternative routes.
  - ▶ For bandwidth, we must equally focus on finding an appropriate node for splitting a TCP connection, thus optimising the transport protocol itself.

## Conclusions

- ▶ Bandwidth is extremely expensive to usefully measure
- ▶ Massive potential for bandwidth improvement can be seen through measurement
- ▶ Deployed detour platform can achieve a significant proportion of this, employing only PlanetLab hosts.
- ▶ Cannot achieve good performance by simply redirecting IP traffic.
- ▶ Approaches for latency detour discovery are not effective for finding bandwidth detours

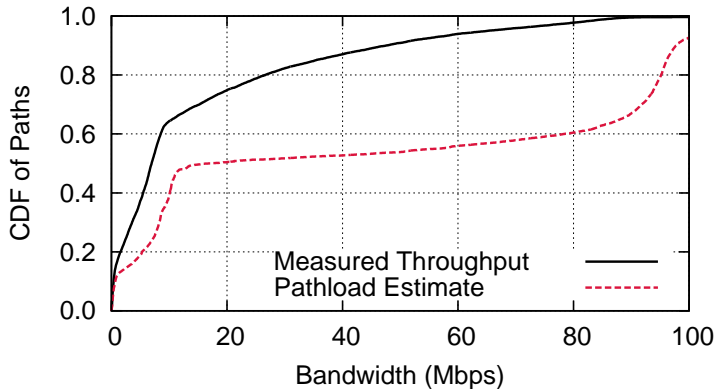

## Conclusions

- ▶ Bandwidth is extremely expensive to usefully measure
- ▶ Massive potential for bandwidth improvement can be seen through measurement
- ▶ Deployed detour platform can achieve a significant proportion of this, employing only PlanetLab hosts.
- ▶ Cannot achieve good performance by simply redirecting IP traffic.
- ▶ Approaches for latency detour discovery are not effective for finding bandwidth detours

Thanks. Questions?
